Implement DNS for Your Application: Set up a DNS record to map your web application's IP or load balancer to a domain name.

Name: S. Jason Peniel Raj

Department: CSE

Introduction

In cloud computing, establishing a proper **Domain Name System (DNS)** configuration is essential for ensuring that applications are accessible over the internet. AWS offers **Route 53**, a highly available and scalable DNS web service, which allows users to manage domain names and point them to AWS resources like EC2 instances. This Proof of Concept (PoC) demonstrates the process of creating and configuring a DNS record in **AWS Route 53**, pointing it to a web server hosted on an **EC2 instance**, thus making the web application accessible via a custom domain name.

Overview

This PoC involves:

1. **Launching an EC2 instance** to serve a web application.
2. **Setting up a web server** (Apache or Nginx) on the EC2 instance to host the application.
3. **Creating a hosted zone** in AWS Route 53 for a custom domain (e.g., myapp.local).
4. **Configuring an A record** in Route 53 to map the domain to the EC2 instance's public IP.
5. **Modifying the hosts file** on a local machine to test the custom domain name before making it publicly available.

6. **Testing the configuration** by accessing the application using the custom domain name.

Objective

The main objectives of this PoC are:

1. **Familiarize with Route 53 DNS configuration:** Understand how to use AWS Route 53 to manage domain names and map them to cloud resources.
2. **Learn EC2 setup and configuration:** Gain hands-on experience in launching an EC2 instance and configuring a web server to serve a web application.
3. **Enable custom domain access:** Configure a custom domain name to point to the EC2 instance, ensuring that the web application is easily accessible through the domain.
4. **Test and verify the configuration:** Ensure that the domain correctly points to the EC2 instance by testing it in a browser and troubleshooting any issues.

Importance

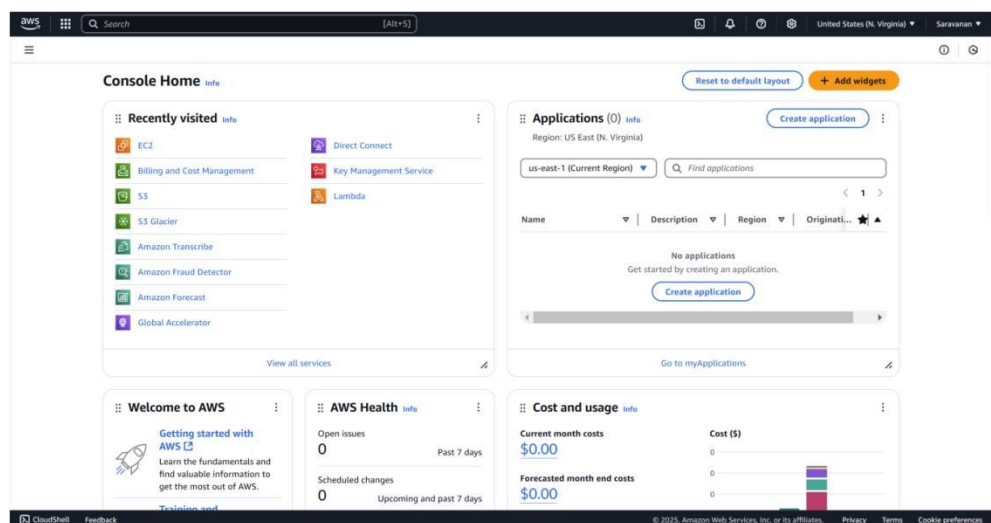

1. **Improves Web Access:** Provides a user-friendly way to access applications via a custom domain.
2. **Scalable DNS Solution:** Route 53 offers scalable and reliable DNS management.

3. **Hands-on Cloud Skills:** Essential for cloud architects and developers to work with AWS services.
4. **Cost-Effective Testing:** Utilizes AWS Free Tier for testing without incurring costs.

Step-by-Step Overview Step

1:

1. Go to [AWS Management Console](#).
2. Enter your username and password to log in.

Step 2:

Launch an instance named **route instance** .

Configure Security Group:

Add a **new security group** with a rule for **HTTP** (port 80) and **SSH** (port 22).

For HTTP, set the source to **Anywhere (0.0.0.0/0)** to allow access via the web.

For SSH, set the source to your **IP** (recommended for security), or use **Anywhere** for now.

Create a Key Pair (or use an existing one) and download the key file (.pem).

Review and click **Launch**.

The screenshot shows the AWS Management Console interface. On the left, the navigation menu includes Dashboard, EC2 Global View, Events, and a list of services under 'Instances' (Instances, Instance Types, Launch Templates, Spot Requests, Savings Plans, Reserved Instances, Dedicated Hosts, Capacity Reservations), 'Images' (AMIs, AMI Catalog), 'Elastic Block Store' (Volumes, Snapshots, Lifecycle Manager), and 'Network & Security' (Security Groups, Elastic IPs, Placement Groups, Key Pairs). The main content area is titled 'Instances (1/1) Info' and shows a table with one instance: 'route instance' with ID 'i-004154969b120bb8c', state 'Running', type 't2.micro', and public IP 'ec2-52-91-79-69.con'. Below the table, the details for the selected instance are shown, including the 'Security' tab which displays the IAM Role, Security groups (sg-091ff45e68e5f742f), and Inbound rules. The bottom of the console shows the footer with copyright information and links to Privacy, Terms, and Cookie preferences.

The screenshot displays the AWS Management Console interface for a security group. The left-hand navigation pane includes sections for Dashboard, EC2 Global View, Events, Instances, Images, Elastic Block Store, and Network & Security. The main content area is titled 'sg-091ff45e68e5f742f - launch-wizard-29'. It features a 'Details' section with key information: Security group name (launch-wizard-29), Security group ID (sg-091ff45e68e5f742f), Description (launch-wizard-29 created 2025-02-09T18:07:45.652Z), VPC ID (vpc-0f36f0944c12862e5), Owner (343218194491), Inbound rules count (2 Permission entries), and Outbound rules count (1 Permission entry). Below this, there are tabs for Inbound rules, Outbound rules, Sharing - new, VPC associations - new, and Tags. The 'Inbound rules (2)' tab is active, showing a table with two rules. The table has columns for Name, Security group rule ID, IP version, Type, Protocol, Port range, and Scope. The first rule is for SSH (Type) over TCP (Protocol) on port 22 (Port range), with a scope of 0.0.0.0/0. The second rule is for HTTP (Type) over TCP (Protocol) on port 80 (Port range), also with a scope of 0.0.0.0/0. At the bottom of the console, there is a footer with 'CloudShell', 'Feedback', and copyright information for Amazon Web Services, Inc. or its affiliates.

sg-091ff45e68e5f742f - launch-wizard-29

Details

Security group name launch-wizard-29	Security group ID sg-091ff45e68e5f742f	Description launch-wizard-29 created 2025-02-09T18:07:45.652Z	VPC ID vpc-0f36f0944c12862e5
Owner 343218194491	Inbound rules count 2 Permission entries	Outbound rules count 1 Permission entry	

Inbound rules (2)

Name	Security group rule ID	IP version	Type	Protocol	Port range	Scope
-	sgr-08cd3a57f47836e47	IPv4	SSH	TCP	22	0.0.0.0/0
-	sgr-0fe112bc7cae9defb	IPv4	HTTP	TCP	80	0.0.0.0/0

Step 3:

Click the 'Connect' option on your launched instance, go to the SSH client section, and copy the command provided under the 'Example' section.

```
sudo yum install httpd -y
```

```
[ec2-user@ip-172-31-82-55 ~]$ sudo yum install httpd -y
```

Step 6:

Start Apache:

sudo systemctl start httpd Make

Apache start on boot:

sudo systemctl enable httpd

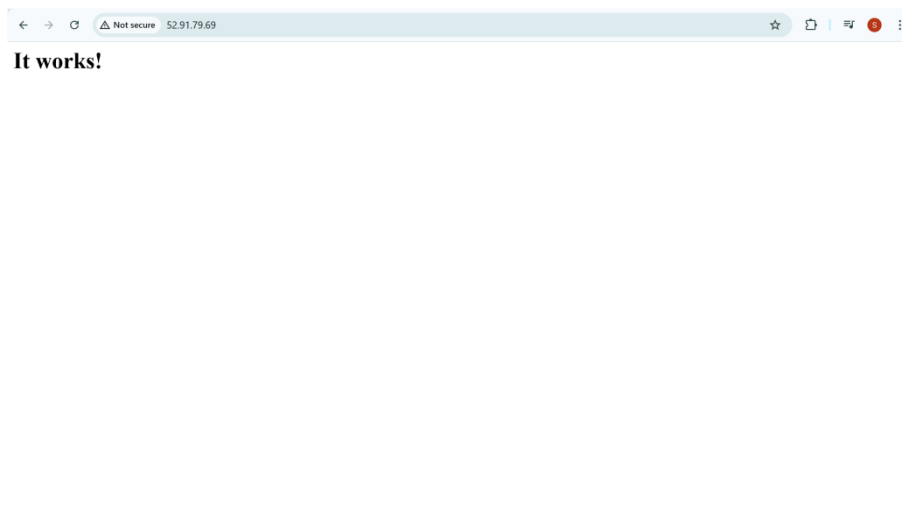

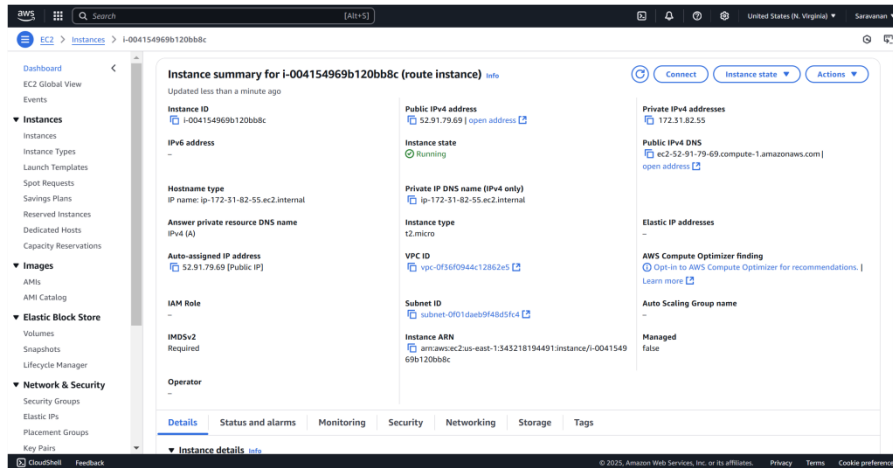

```
[ec2-user@ip-172-31-82-55 ~]$ sudo systemctl start httpd  
[ec2-user@ip-172-31-82-55 ~]$ sudo systemctl enable httpd
```

Step 7:

Verify Apache is running:

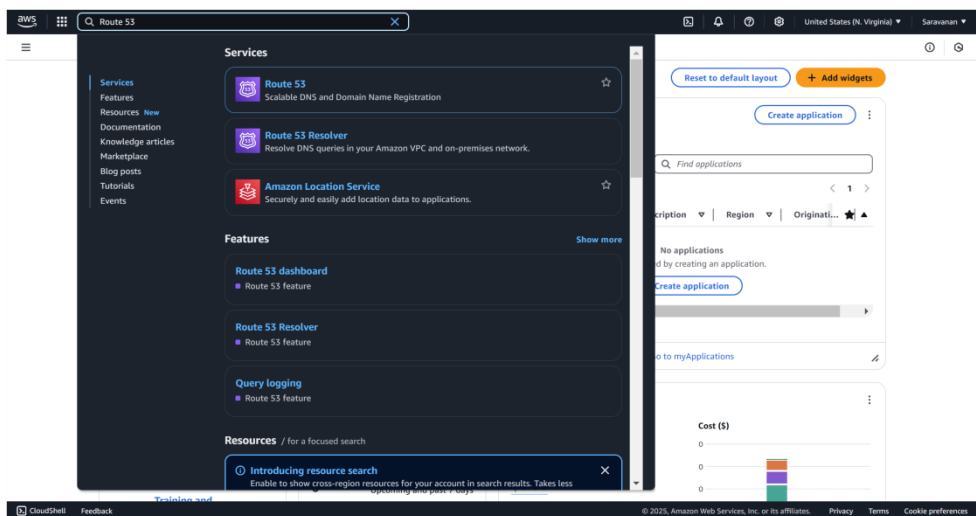

In your browser, enter the **EC2 public IP** (e.g., `http://<your-ec2public-ip>`).

You should see the **Apache default page**. This means your EC2 instance is set up to serve websites.

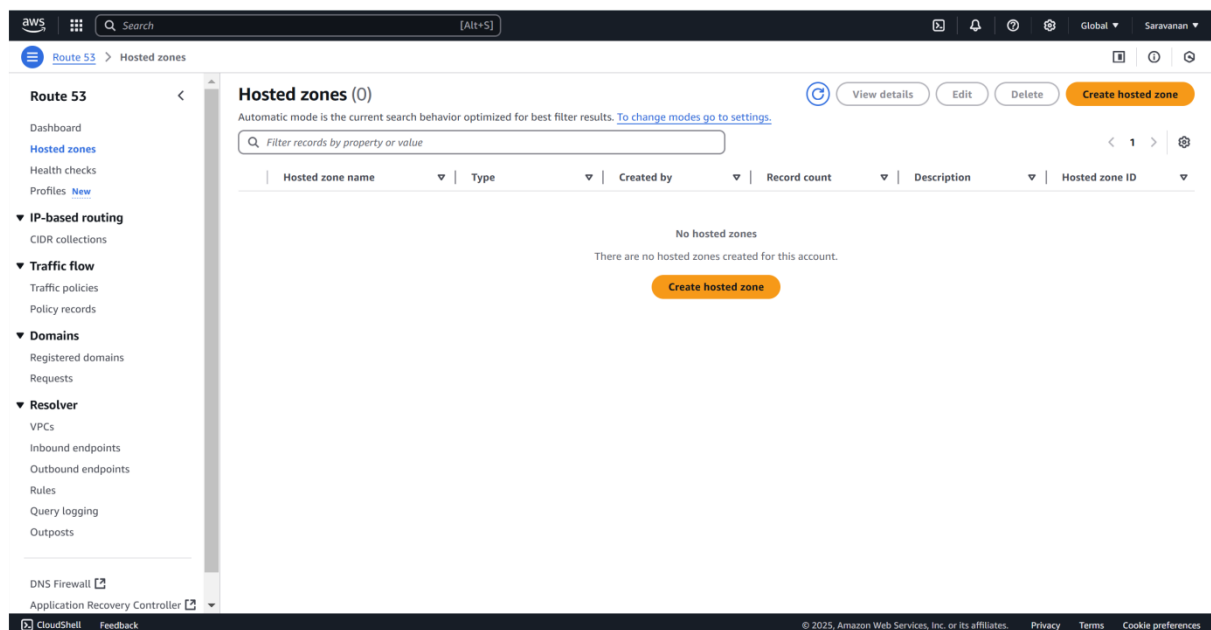

Step 8:

In the AWS Console, search for **Route 53** and select it.

Step 10:

1. Click on **Create hosted zone**.
2. Enter a **Domain Name** (e.g., myapp.local).
3. Set the **Type** to **Public Hosted Zone**.
4. Click **Create hosted zone**.

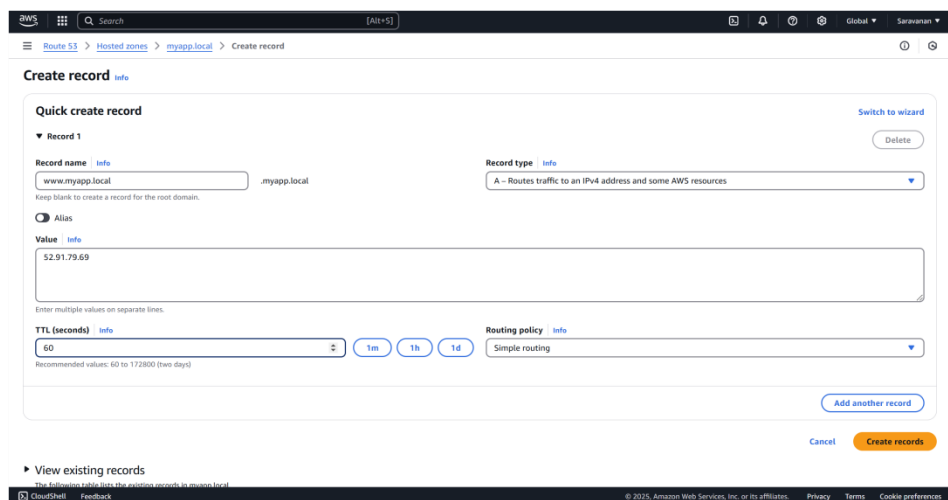

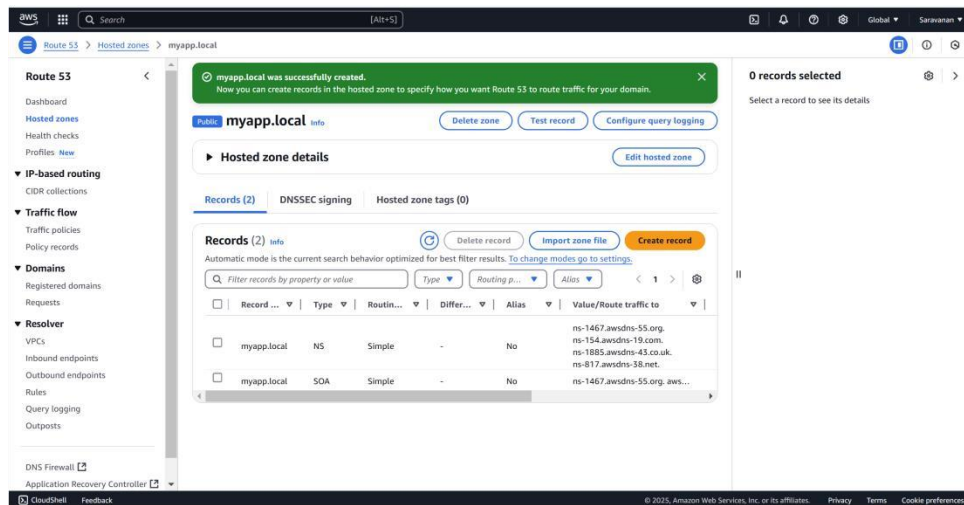

Step 11:

The screenshot shows the AWS Management Console interface for creating a hosted zone. The breadcrumb navigation at the top indicates the path: Route 53 > Hosted zones > Create hosted zone. The main heading is 'Create hosted zone' with an 'info' link. Below this, the 'Hosted zone configuration' section explains that a hosted zone is a container for routing traffic. It contains two input fields: 'Domain name' (pre-filled with 'myapp.local') and 'Description - optional' (pre-filled with 'POC for DNS setup'). Below the description field, it states 'The description can have up to 256 characters. 17/256'. The 'Type' section has two radio buttons: 'Public hosted zone' (selected) and 'Private hosted zone'. The 'Tags' section is titled 'Tags' and states 'Apply tags to hosted zones to help organize and identify them. No tags associated with the resource.' There is an 'Add tag' button and a note 'You can add up to 50 more tags.' The footer of the console shows 'CloudShell', 'Feedback', and copyright information for Amazon Web Services, Inc. or its affiliates, along with links for 'Privacy', 'Terms', and 'Cookie preferences'.

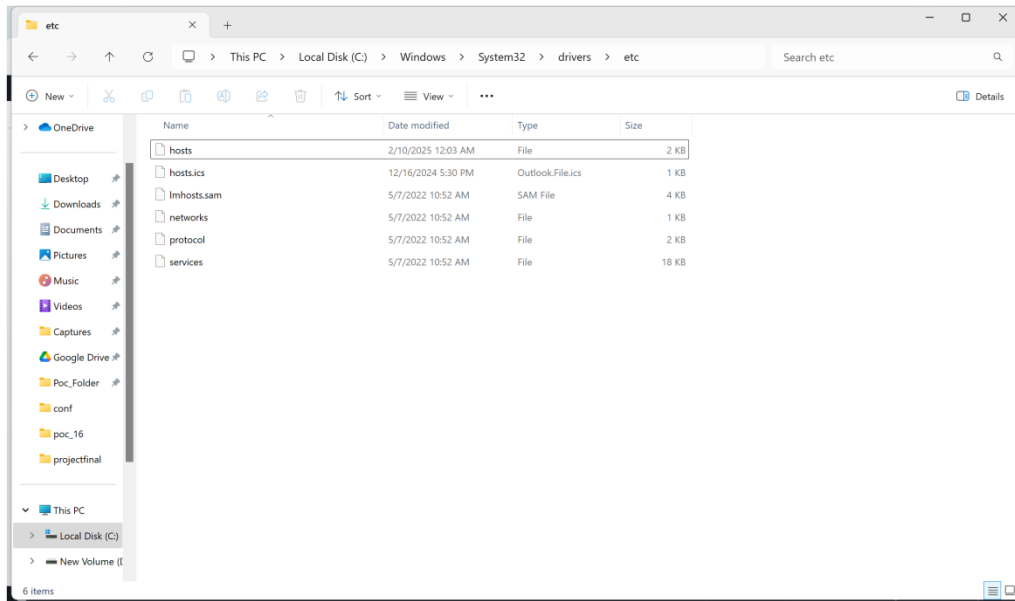

1. In your hosted zone, click **Create Record**.
2. **Record Name**: Leave it empty for the root domain (myapp.local),
3. **Record Type**: Select **A – IPv4 address**.
4. **Value**: Enter the **Public IP** of your EC2 instance.
5. **TTL**: Set to 60 seconds.
6. Click **Create records**.

Step 12:

1. Go to **FileExplorer** > **Open**.
2. Navigate to: **C:\Windows\System32\drivers\etc**.
3. In the file name field, type **hosts** and press **Enter**.

Step 13:

Step 12:

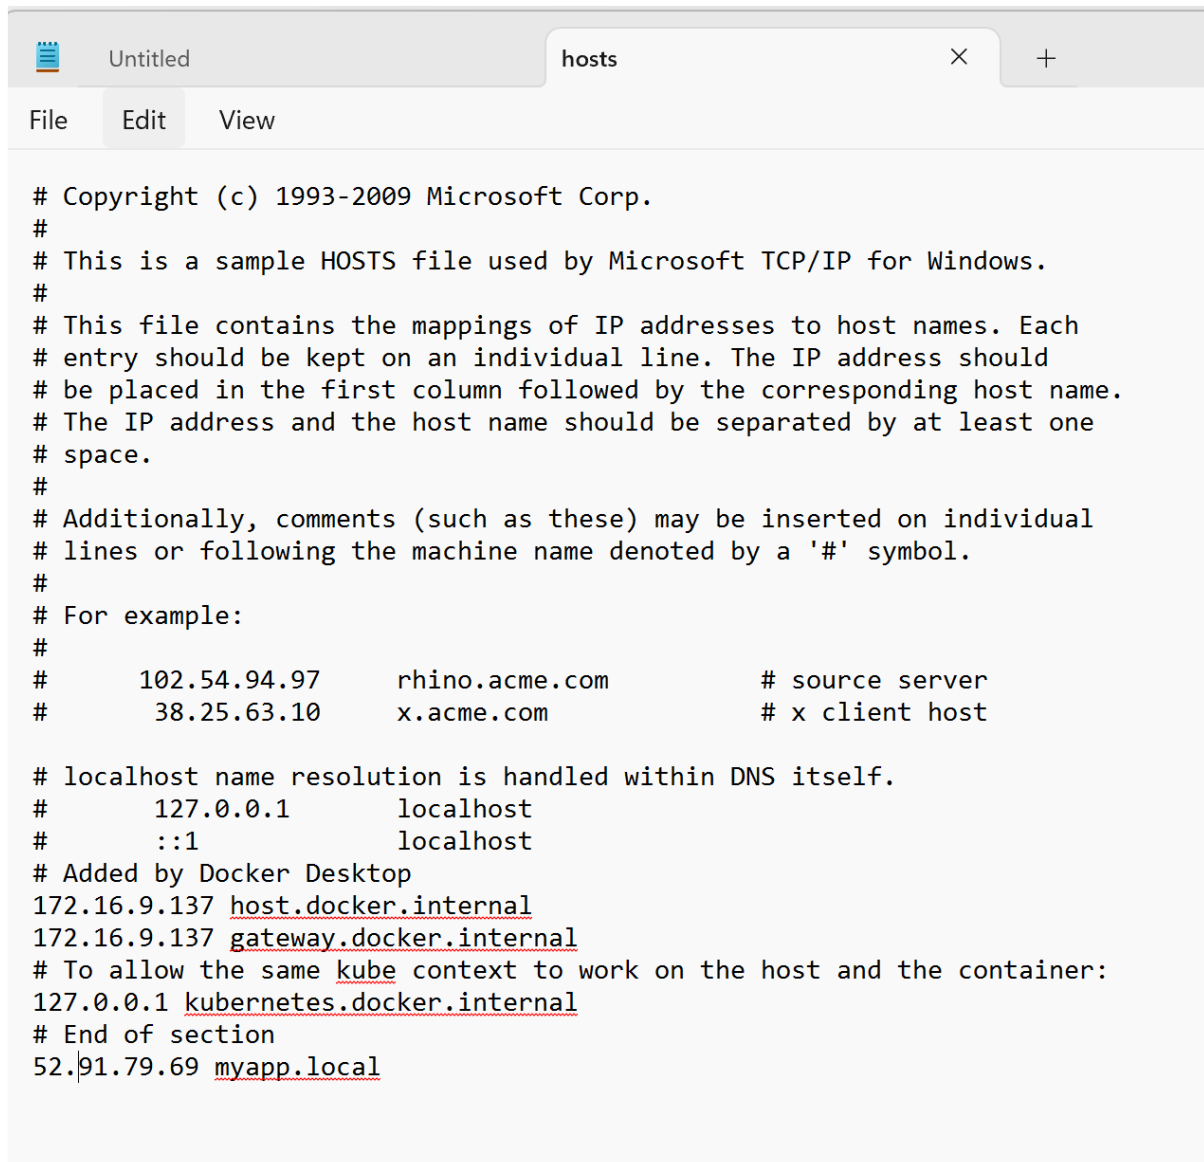

1. At the bottom of the file, add:

<Your EC2 Public IP> myapp.local

Replace <Your EC2 Public IP> with the public IP you copied.

(Eg: 52.91.79.69 myapp.local)

2. Save the file and close Notepad.

```
# Copyright (c) 1993-2009 Microsoft Corp.
#
# This is a sample HOSTS file used by Microsoft TCP/IP for Windows.
#
# This file contains the mappings of IP addresses to host names. Each
# entry should be kept on an individual line. The IP address should
# be placed in the first column followed by the corresponding host name.
# The IP address and the host name should be separated by at least one
# space.
#
# Additionally, comments (such as these) may be inserted on individual
# lines or following the machine name denoted by a '#' symbol.
#
# For example:
#
#       102.54.94.97       rhino.acme.com          # source server
#       38.25.63.10       x.acme.com              # x client host

# localhost name resolution is handled within DNS itself.
#       127.0.0.1         localhost
#       ::1               localhost
# Added by Docker Desktop
172.16.9.137 host.docker.internal
172.16.9.137 gateway.docker.internal
# To allow the same kube context to work on the host and the container:
127.0.0.1 kubernetes.docker.internal
# End of section
52.91.79.69 myapp.local
```

Step 12:

Open your **web browser**.

Type myapp.local in the address bar and press **Enter**.

You should see the Apache default page

Outcome

By completing this PoC of configuring DNS for your application using AWS Route 53 and EC2, you will:

1. Launch and configure an EC2 instance with a web server (e.g., Apache or Nginx).
2. Deploy a sample web application on the EC2 instance and ensure it is accessible via the instance's public IP.
3. Create a hosted zone in AWS Route 53 for DNS management.
4. Set up an A record in Route 53 to map your custom domain (e.g., myapp.local) to the EC2 instance's public IP.
4. Modify the local hosts file on your system to resolve the custom domain name locally for testing.

5. Successfully access your web application using the custom domain name in a browser.
